Systematic Reviews and Meta-analysis

Introduction to Clinical Research:
A Two-week Intensive Course
July 17, 2013

Sonal Singh, MD, MPH Assistant Professor

Key messages

- Systematic reviews (SR) summarize existing evidence for a specific research question.
- SR are important to identify research gaps and limitations of previous studies, to justify new research and to inform decision makers.
- Meta-analyses provide summary estimates from different studies and are based on effect and variance estimates.

2

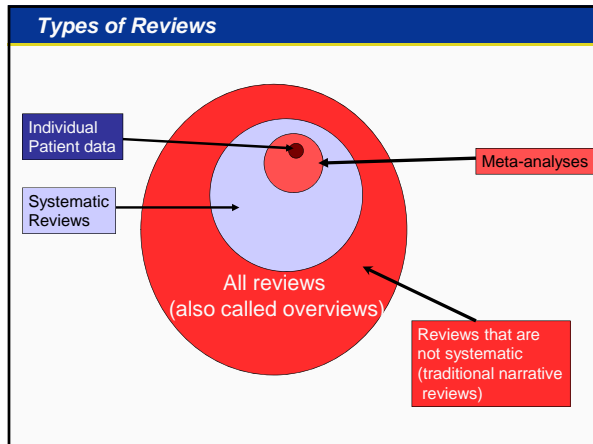

Definition of a systematic review

A review of existing evidence that uses a explicit and scientific methods

Contains a clear description of:

- Research question preferably using PICOTS
- Inclusion/exclusion criteria for studies
- Process used to identify studies
- Methods used to assess quality
- Methods use to abstract and summarize data

May or may not combine data quantitatively (meta-analysis)

Types of questions addressed by systematic reviews

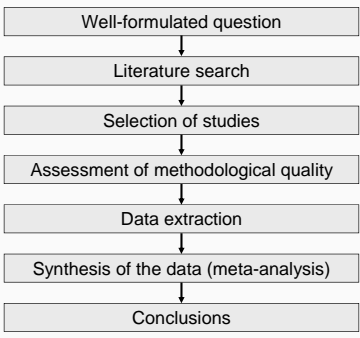

Research questions	Type of studies included
Etiology (some exposure disease association)	Cohort or case-control studies
Diagnostic tests	Test accuracy studies, (RCTs)
Therapy	RCTs, observational studies
Prognosis (some predictor outcome association)	Cohort studies
Outcome measurement	Measurement studies
...	...

- Roles of systematic reviews II**
- Justification of new research, scientifically and ethically
 - Learn about challenges of previous studies → avoid problems
 - Inform decision makers
 - Become an expert in topic
 - Have another publication
- 6

The steps of a systematic reviews

Ingredients of a systematic review

```
graph TD; A[Well-formulated question] --> B[Literature search]; B --> C[Selection of studies]; C --> D[Assessment of methodological quality]; D --> E[Data extraction]; E --> F[Synthesis of the data (meta-analysis)]; F --> G[Conclusions];
```

8

Well-formulated question

Example

Population	Tobacco users
Intervention	Varenicline
Comparator	Placebo or active control (Nicotine replacement therapy or bupropion
Outcome	Serious adverse cardiovascular events

9

 **Outcomes**

Primary Outcome : Any serious ischemic or arrhythmic cardiovascular event reported during the double blind period of the trial [composite]
Secondary outcome : All cause mortality

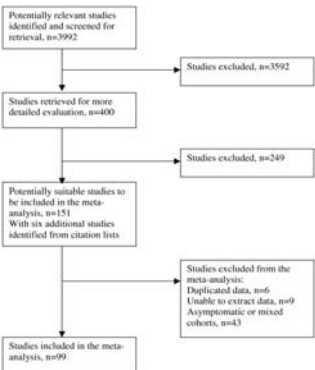

July 18, 2013 Presented by: Smital Singh, MD MPH
Singh S et al. CMAJ 2011;183:1359-1366 

Identification of Articles

- Work with a librarian!
- Search in multiple databases, at least Medline and EMBASE
- Many studies not in English (>> than for RCTs)
- Hand-searching when time and resources available

11

Example for study flow

```
graph TD; A[Potentially relevant studies identified and screened for retrieval, n=3992] --> B[Studies retrieved for more detailed evaluation, n=400]; A --> C[Studies excluded, n=3592]; B --> D[Potentially suitable studies to be included in the meta-analysis, n=151  
With six additional studies identified from citation lists]; B --> E[Studies excluded, n=249]; D --> F[Studies included in the meta-analysis, n=99]; D --> G[Studies excluded from the meta-analysis:  
- Duplicated data, n=6  
- Unable to extract data, n=9  
- Asymptomatic or mixed cohorts, n=43];
```

Meta-analysis

What is a Meta-analysis?

- An **optional** component of a systematic review
- Definition: "the statistical analysis of a large collection of analysis results from individual studies for the purpose of integrating the findings." (Glass 1976)

Presentation: the Forest Plot

Estimates with 95% confidence intervals

Kennedy 1997

Locke 1952A

Lopes 1997

Reynolds 1998

Seiberth 1994

Line of no effect

Estimate and confidence interval for each study

Estimate and confidence for the meta-analysis

Scale (effect measure)

Risk ratio

0.2 1.0 5

Favours LR ← → Favours control

Direction of effect

21

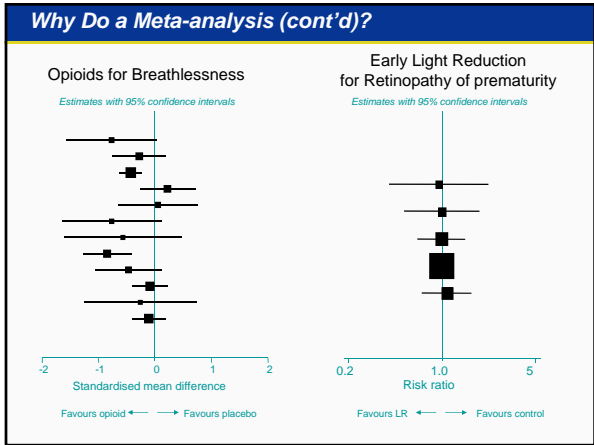

Inverse-variance Weighted Average

- Require from each study
 - estimate of treatment effect; and
 - standard error (or variance) of estimate
- Combine these using a weighted average:

$$\text{weighted average} = \frac{\text{sum of (estimate} \times \text{weight)}}{\text{sum of weights}} = \frac{\sum Y_i W_i}{\sum W_i}$$

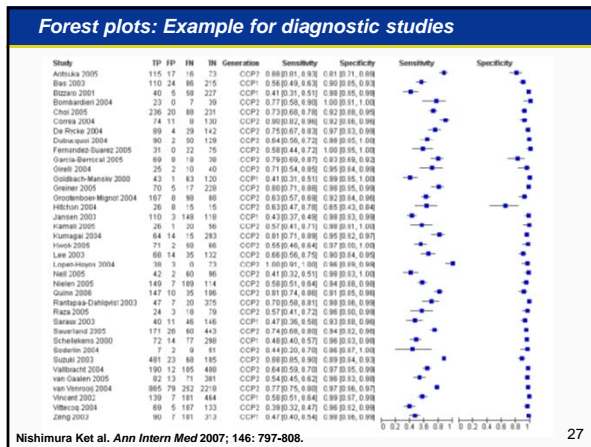

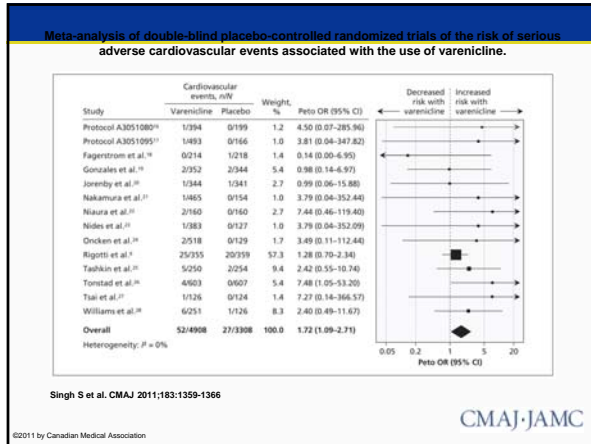

$$\text{Variance (weighted average)} = \frac{1}{\text{sum of weights}} = \frac{1}{\sum W_i}$$

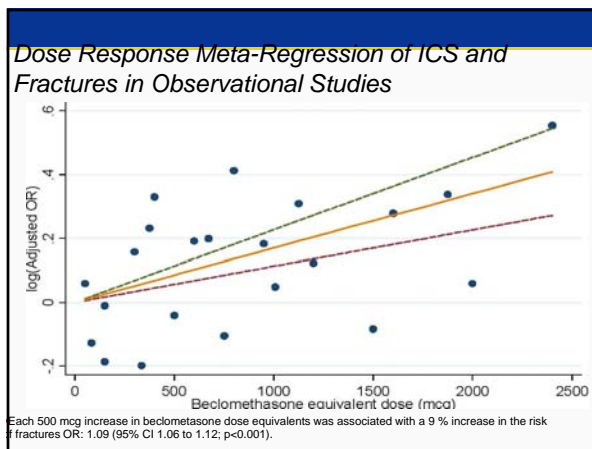

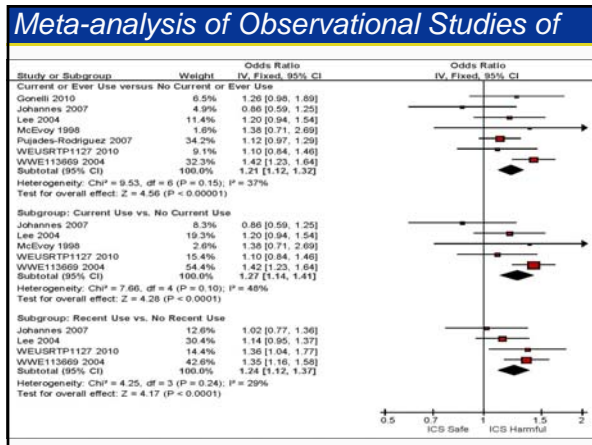

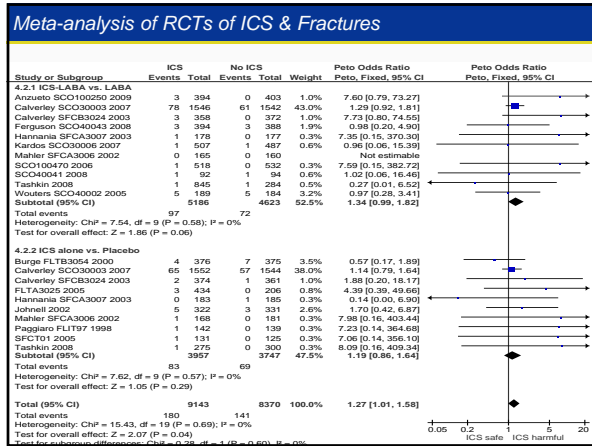

Y_i - intervention effect estimated in the i th study
 W_i - weight given to the i th study, and is usually chosen to be the inverse of the variance of the effect estimate

Why Do a Meta-analysis (cont'd)?

- To increase power and precision
 - detect effect as statistically significant; narrower CIs
- To quantify effect sizes and their uncertainty
 - reduce problems of interpretation due to sampling variation
- To assess homogeneity/heterogeneity of results
 - quantify between-study variation
- To answer questions not posed by the individual studies
 - factors that differ across studies
- To settle controversies arising from conflicting studies
 - generate new hypotheses

When Not to Do a Meta-analysis

- **“Garbage in - garbage out”**
 - a meta-analysis is only as good as the studies in it
 - narrower confidence interval around combination of biased studies worse than the biased studies on their own
 - beware of reporting biases (e.g. publication bias)
- **“Mixing apples with oranges”**
 - not useful for learning about apples, although useful for learning about fruit!
 - studies must address the same question
 - ▶ though the question can, *and usually must*, be broader

Number Needed to Harm for Cardiovascular Events based on Meta-analysis

Population	Source of baseline risk	Baseline Risk	Annualized Number Needed to Harm
Smokers without CVD	Control event rate of Meta-analysis	0.82%	167
Smokers with stable CVD	Control event rate of trial among smokers with CVD	5.8%	28

Presented by: David Sacks, MD, MPH
 July 18, 2013
 Singh S et al. CMAJ 2011;183:1359-1366

Limitations

- Trials did not use adjudicated CV definitions
- Could not conduct time to event analysis due to individual patient data

Conclusions

- Among smokers exposure to varenicline is associated with a statistically significant increased risk of CV events

Key messages

- Systematic reviews (SR) summarize existing evidence for a specific research question.
- SR are important to identify research gaps and limitations of previous studies, to justify new research and to inform decision makers.
- Meta-analyses provide summary estimates from different studies and are based on effect and variance estimates.
